

APAC Business-tier churn: a hidden, fixable revenue leak

Product Operations · Prepared for: CS & Product leadership · Source: 12,080-user retention analysis

BOTTOM LINE

One segment — **Business-plan accounts in APAC** — is churning at **30%**, nearly double the **17.9%** company average. The gap opened in fall 2024 alongside a spike in support tickets and a drop in satisfaction, pointing to a regional product issue rather than pricing. It puts **~\$178K in monthly revenue at risk**; a targeted retention effort could recover an estimated **~\$850K/year**. Next step: launch a save-play for this segment and open an engineering investigation into the APAC scheduling sync.

The problem

Company-wide churn sits at 17.9% — a flat number that, on its own, gives leadership nothing to act on. The question was whether that average hides a specific, addressable pocket of loss.

What the analysis found

Churn was tested across all 16 plan × region segments, each compared against the rest of the customer base and corrected for multiple comparisons. Exactly one segment cleared both the significance bar and a materiality bar (≥1.4× the average): Business-tier customers in APAC, at 30.1% churn (n = 409). The remaining 15 segments were within normal range — which is what makes this one credible rather than cherry-picked.

Three independent signals corroborate a product cause, not a pricing one:

Signal	Flagged segment	Everyone else
Churn rate	30.1%	17.9% (avg)
Satisfaction (CSAT, 1–5)	3.0	4.0
Support tickets per user	3.1× higher	baseline
When it started	Fall 2024	stable

A regional, tier-specific spike that begins at a discrete point in time and shows up in tickets and satisfaction as well as churn is the signature of a product defect — most likely in the APAC scheduling sync.

Why it matters (in dollars)

- **\$177,509 / month** in recurring revenue sits with still-active accounts in this segment — revenue at risk if the churn trend continues.
- **~\$852,000 / year** is the estimated recoverable revenue from a retention effort, assuming a 40% save rate. (The save rate is an explicit planning assumption, not a measured result.)

Recommendation

- **Launch a targeted save-play** for active Business/APAC accounts — proactive outreach plus support prioritization — before they reach the churn point.
- **Open an engineering investigation** into the APAC scheduling sync, scoped to the fall-2024 onset window flagged above.
- **Frame the save-play as a measurable test** — defined cohort, control group, and a target reduction in the segment’s churn rate — so the intervention proves its own ROI.

What to monitor

The analysis reruns on each new export. Rerun the same test monthly and alert whenever any plan × region segment crosses both bars — so the next pocket is caught in weeks, not after the revenue is gone.

Note: figures are drawn from a synthetic dataset built for portfolio demonstration; the method and memo structure are what a live investigation would produce.
